

EVALUATING THE HYBRID MOBILE SURVEY METHOD (HMS) FOR TIDAL ENERGY RESOURCE ASSESSMENTS

Michelle Kryl, Dr. Kevin Haas, Dr. Budi Gunawan

Wednesday, 13 August 2025

Today's Roadmap

Who I Am

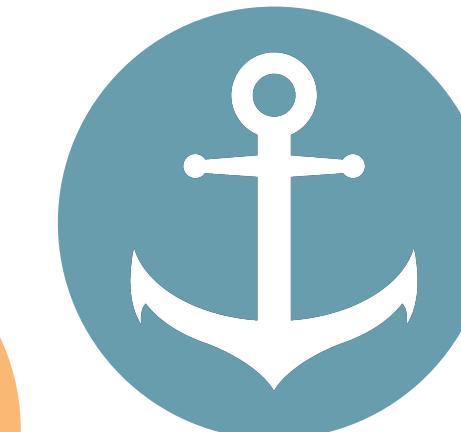

Georgia Tech PhD student
working on tidal energy

Field Deployment &

Instrumentation

40-day fixed instruments
(FI) + 3-day mobile
vessel (MV) surveying

Results: Velocity

Structure & Trends

Flood vs ebb, shear, and
key flow patterns

Why HMS?

Background & Motivation

Why traditional tidal
resource assessment
methods fall short for most
small projects.

Quality Control &

Data Processing

Cleaning, calibrating, and
analyzing instrument data
with MATLAB

Next Steps

Linear Regression
Modeling & Applications

Background

IEC TS 62600-201 (1st Edition)

Direct measurement

- Minimum 90 days of in-situ velocity data at each Tidal Energy Converter (TEC) location
- Harmonic analysis: generate long-term velocity distributions

Hydrodynamic modeling

- 1-year minimum simulation & calibrated with real-world data

Focus: **Estimate Annual Energy Production (AEP) with acceptable uncertainty.**

Limitations

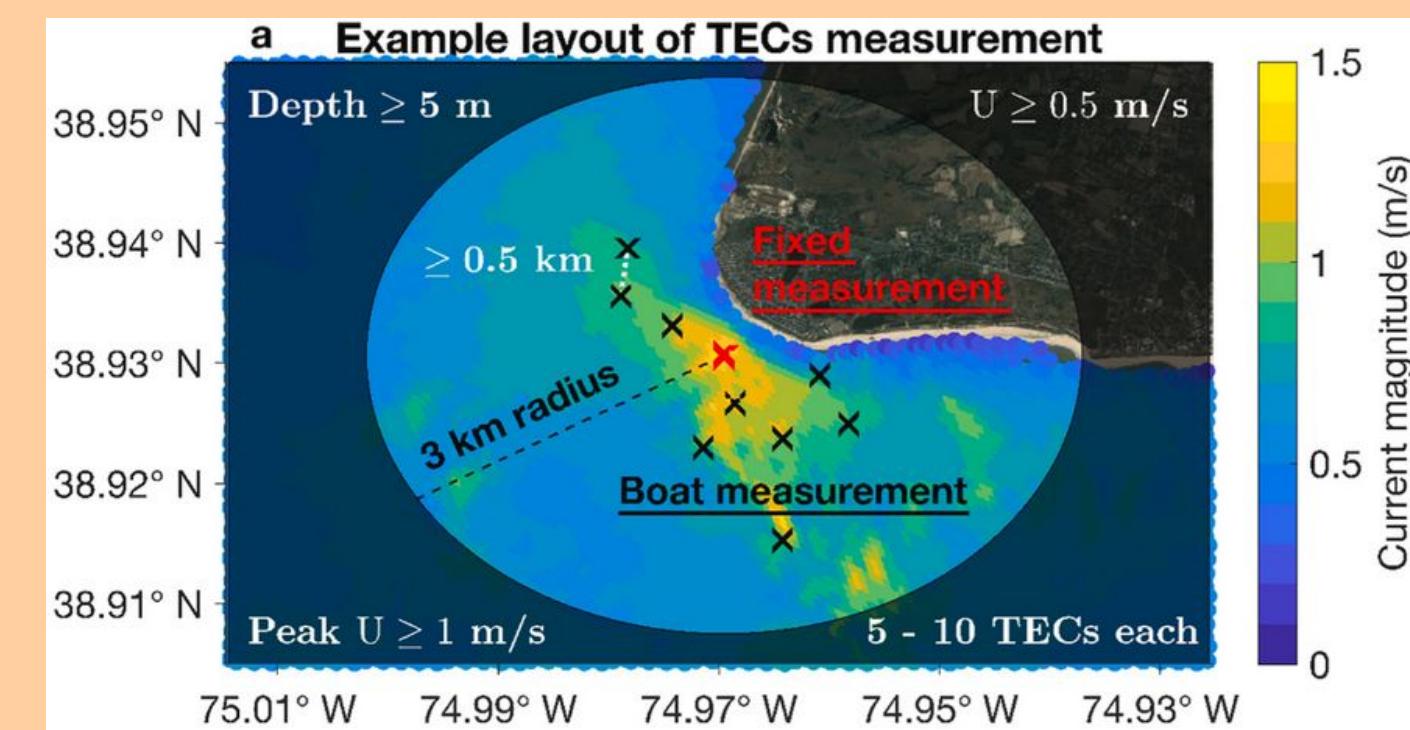

Xu et al. (2023) Large commercial scale OR pilot projects

Evaluated synthetic tidal records (14–196 days) over a 100-year span across multiple locations

- Direct AEP estimates from short periods
- Indirect methods: regression from fixed and mobile vessel measurements

Results:

- Essential to fully resolve multiple spring/neap cycles
- Hybrid method using FI and MV measurements
- **Short vessel-based surveys (HMS) can be effective if calibrated properly**

Xu et al. (2023)

Objective

Perform a field test of the Hybrid Mobile Survey method to be included in the forthcoming 2nd edition TS

Location: Savannah River, Georgia

FI 40-day deployment

- ADCP & Aquadopp (Adopp)
- October 21, 2024

MV Surveying

- 3-day ADCP

~~6 TEC locations~~ 24, 2024

- 5 locations chosen across river channel
- 1 marked location at Adopp

Cycles to each TEC location

- 3-5 minutes of data recording
- Stay within 20m of TEC location
- Full TEC rotation: ~40-60 minutes

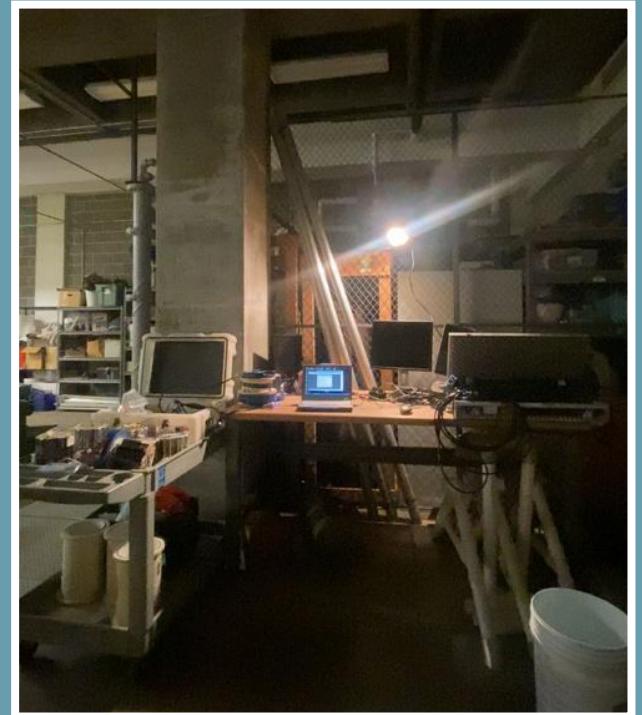

Field Overview & Timeline

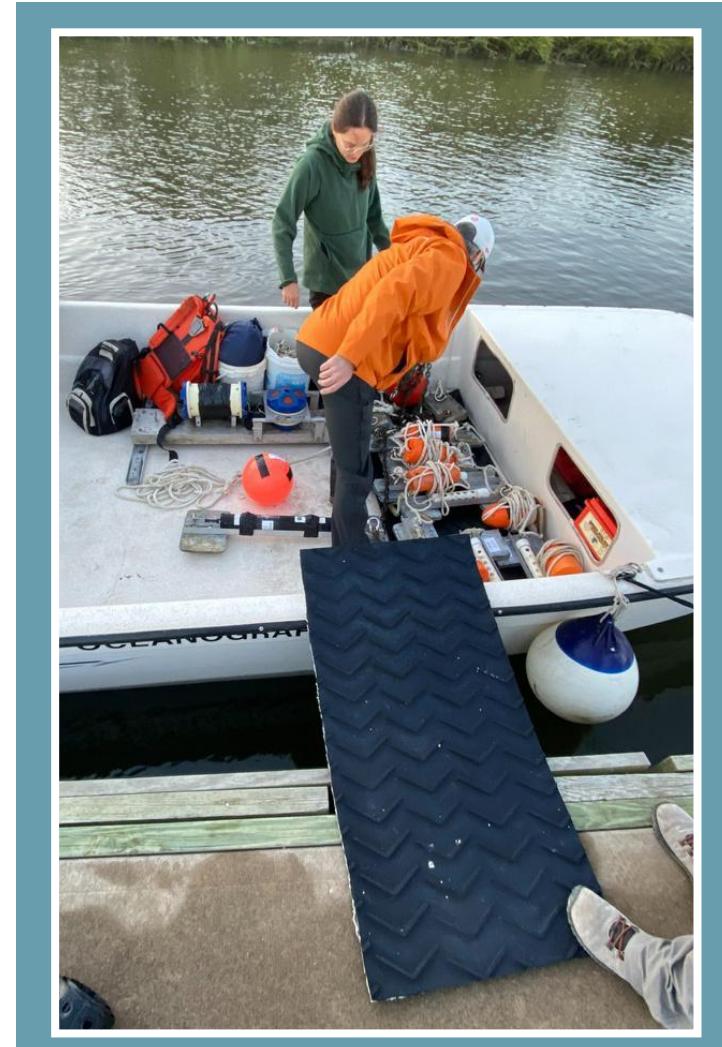

SEPTEMBER

Check and prepare instruments

OCTOBER

Deployment of 2 FI and 3-day MV surveying

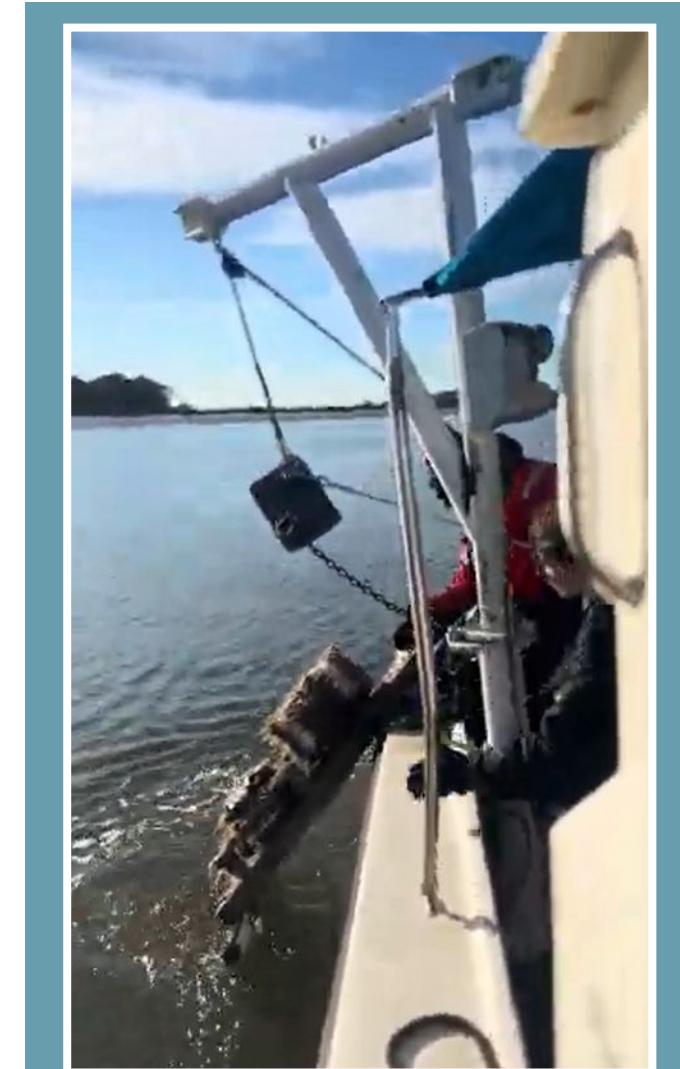

NOVEMBER

Sit patiently and hope the FI's are there in 40 days

DECEMBER

Retrieval of 2 FI's

Fixed Deployment & Instrumentation

October 21, 2024

FI Deployment Preparation

ADCP Workhorse

No divers permitted for deployment

Aquadopp

Testing HMS Method

3-Day Mobile Surveying - October 22-24, 2024

TEC Locations

- GPS tracking with Proflex 500
- TEC locations plugged into HUMMINBIRD
- Base station at Skidaway
- Vessel GPS Mapping (bow and stern)

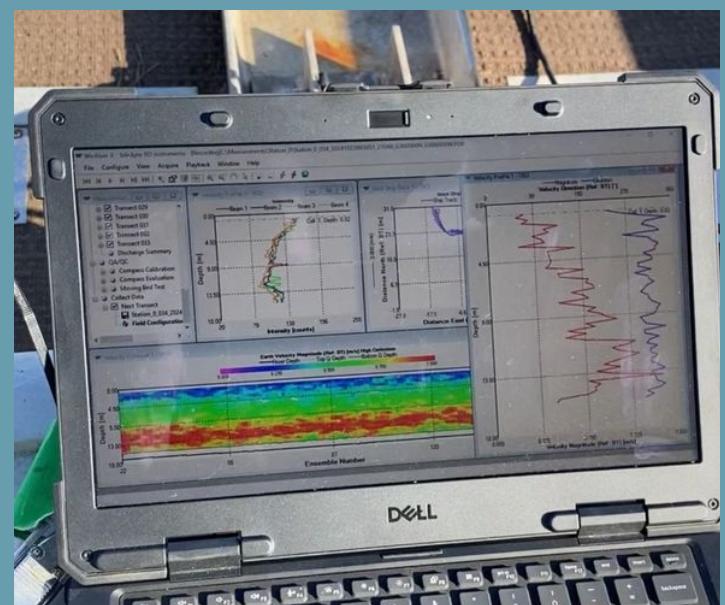

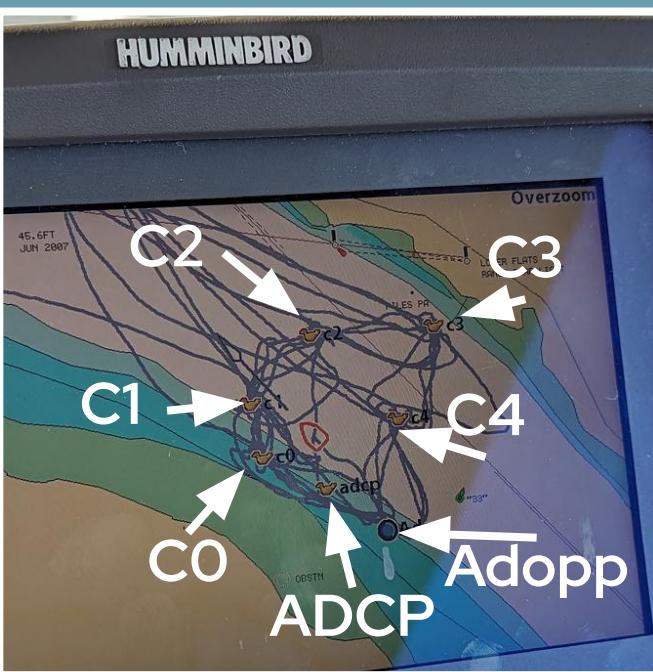

HMS Data Collection

- 6 total Tidal Energy Converter (TEC) stations
 - 5 chosen across channel
 - 1 located at Adopp
- Get \leq 20m of the TEC station
- Start vessel ADCP data collection
- Attempt to stay within 20m of station for 3-5 minutes
- Repeat

MV ADCP

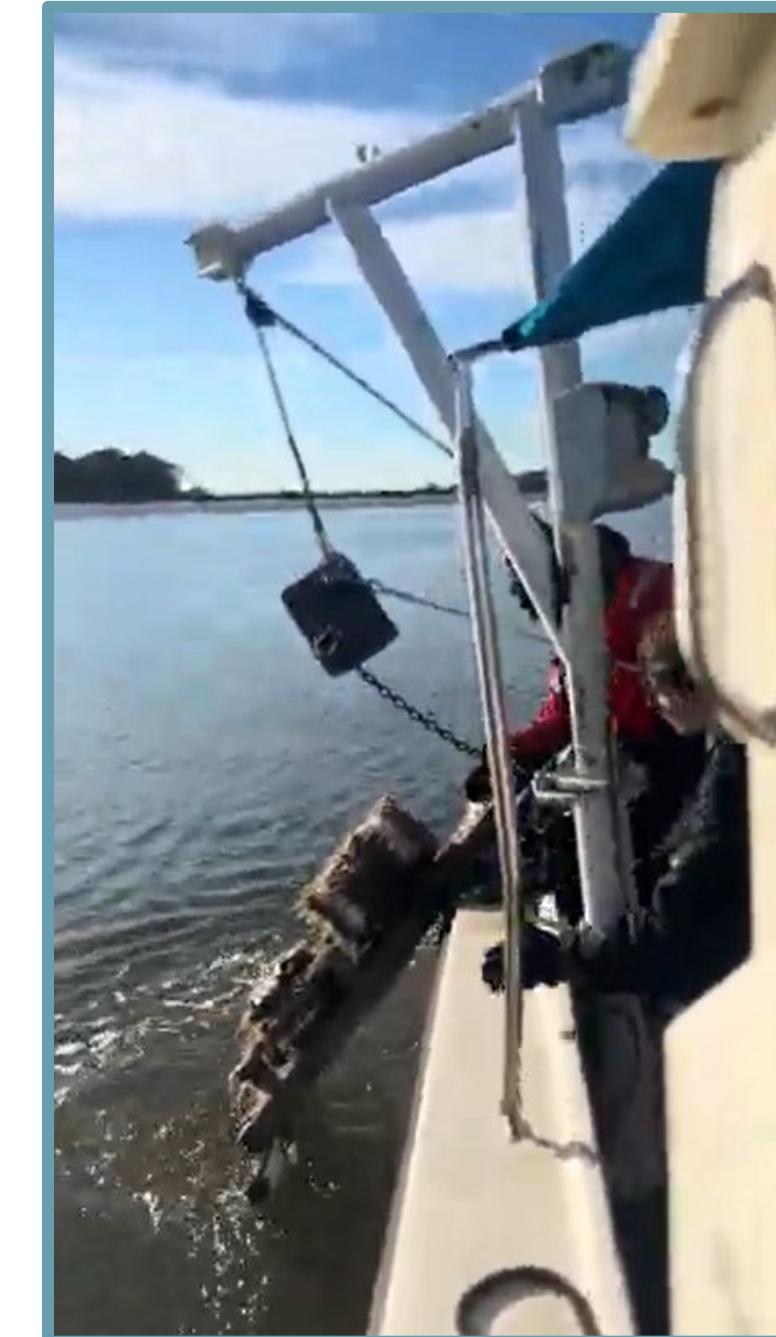

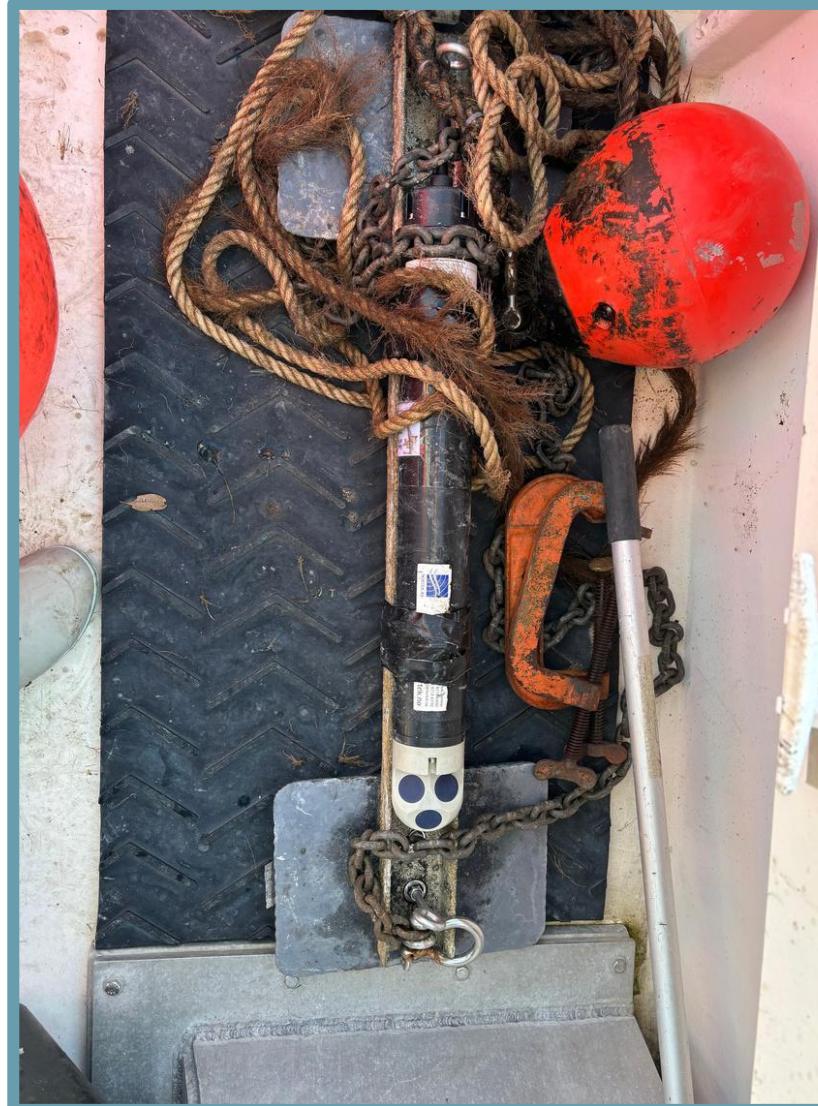

Vessel ADCP Data Collection

Instrument Retrieval

40-day deployment complete: December 2024

Raw Data Quality Control & Initial Observations

Data Recording & Organization

Bin Size

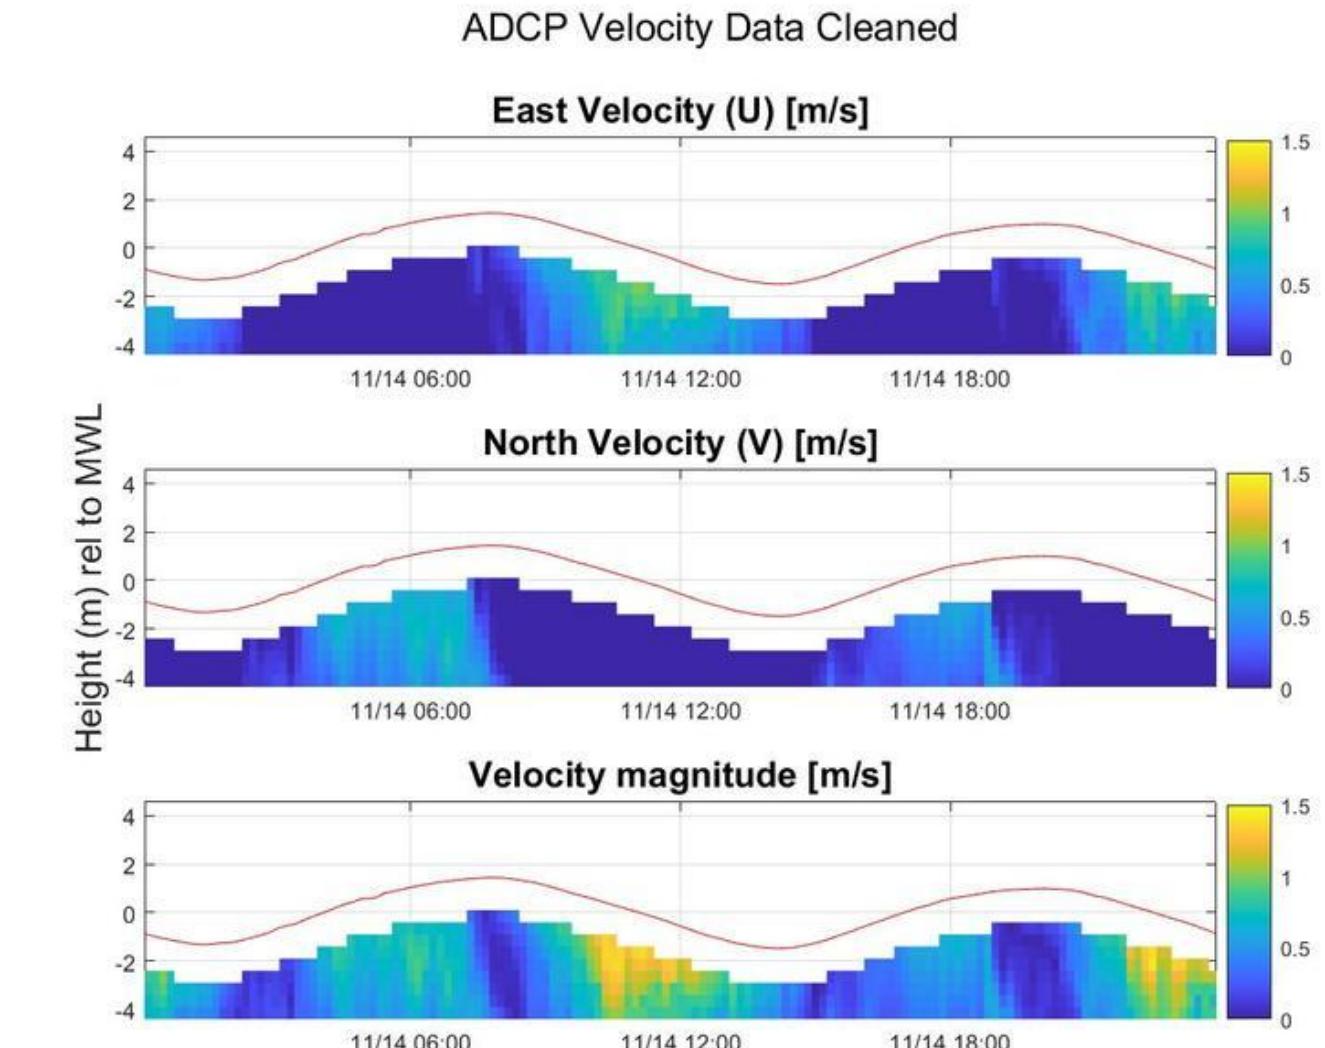

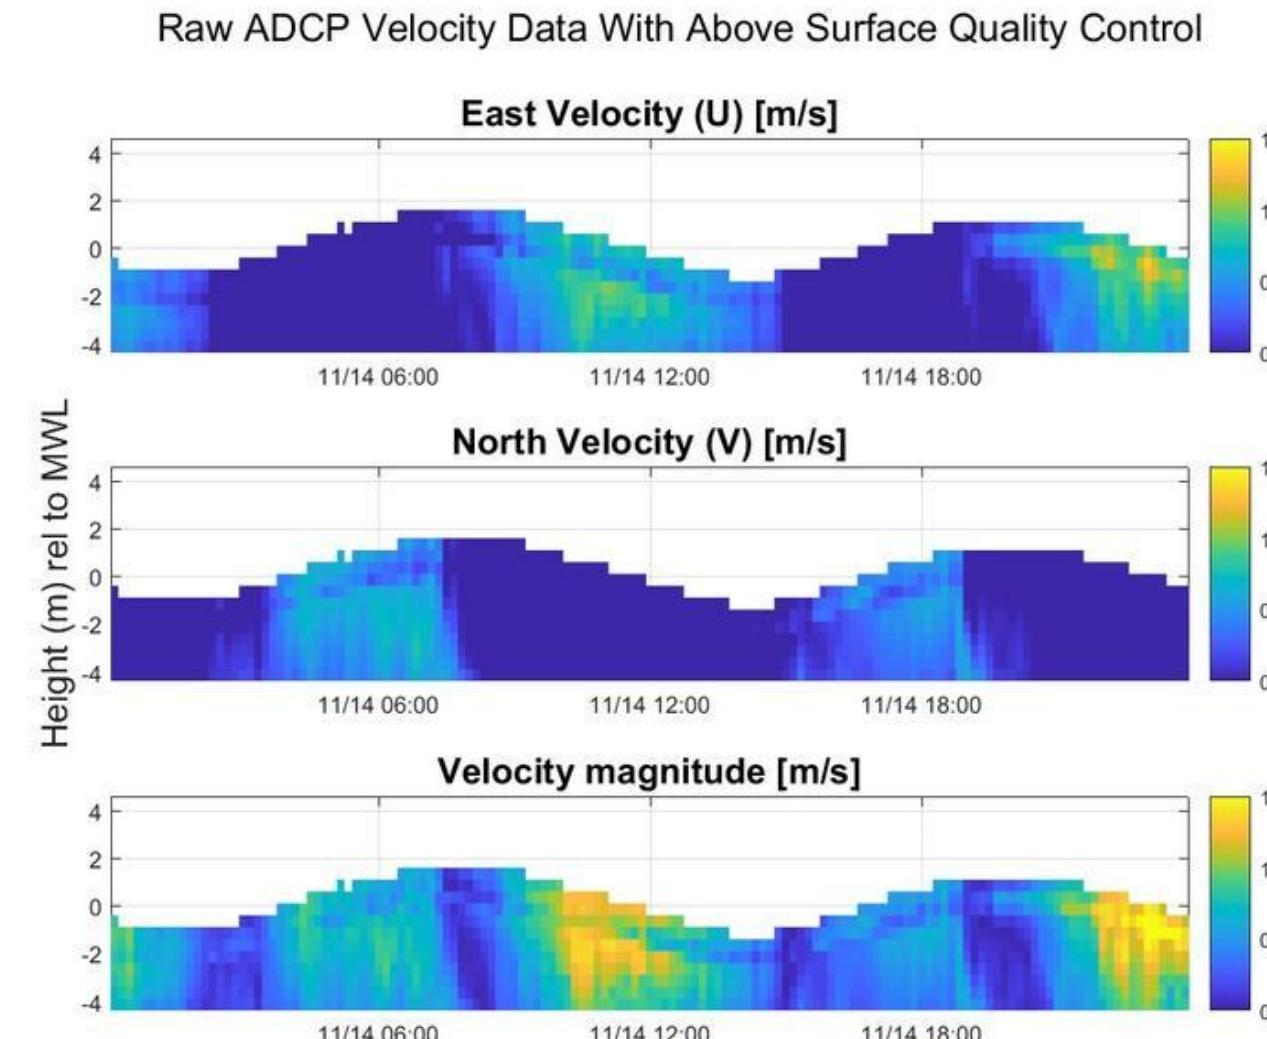

- Fixed: 0.5m (20 total)
- Vessel: 0.1m

Sampling Rate

- Fixed
 - 3 min average; 10 min interval
- Vessel
 - 2 Hz; 3-7 minutes per TEC location

Quality Control

- Remove outliers and bad data bins
 - Interpolate removed data points
- Remove surface noise
- Remove sidelobe interference

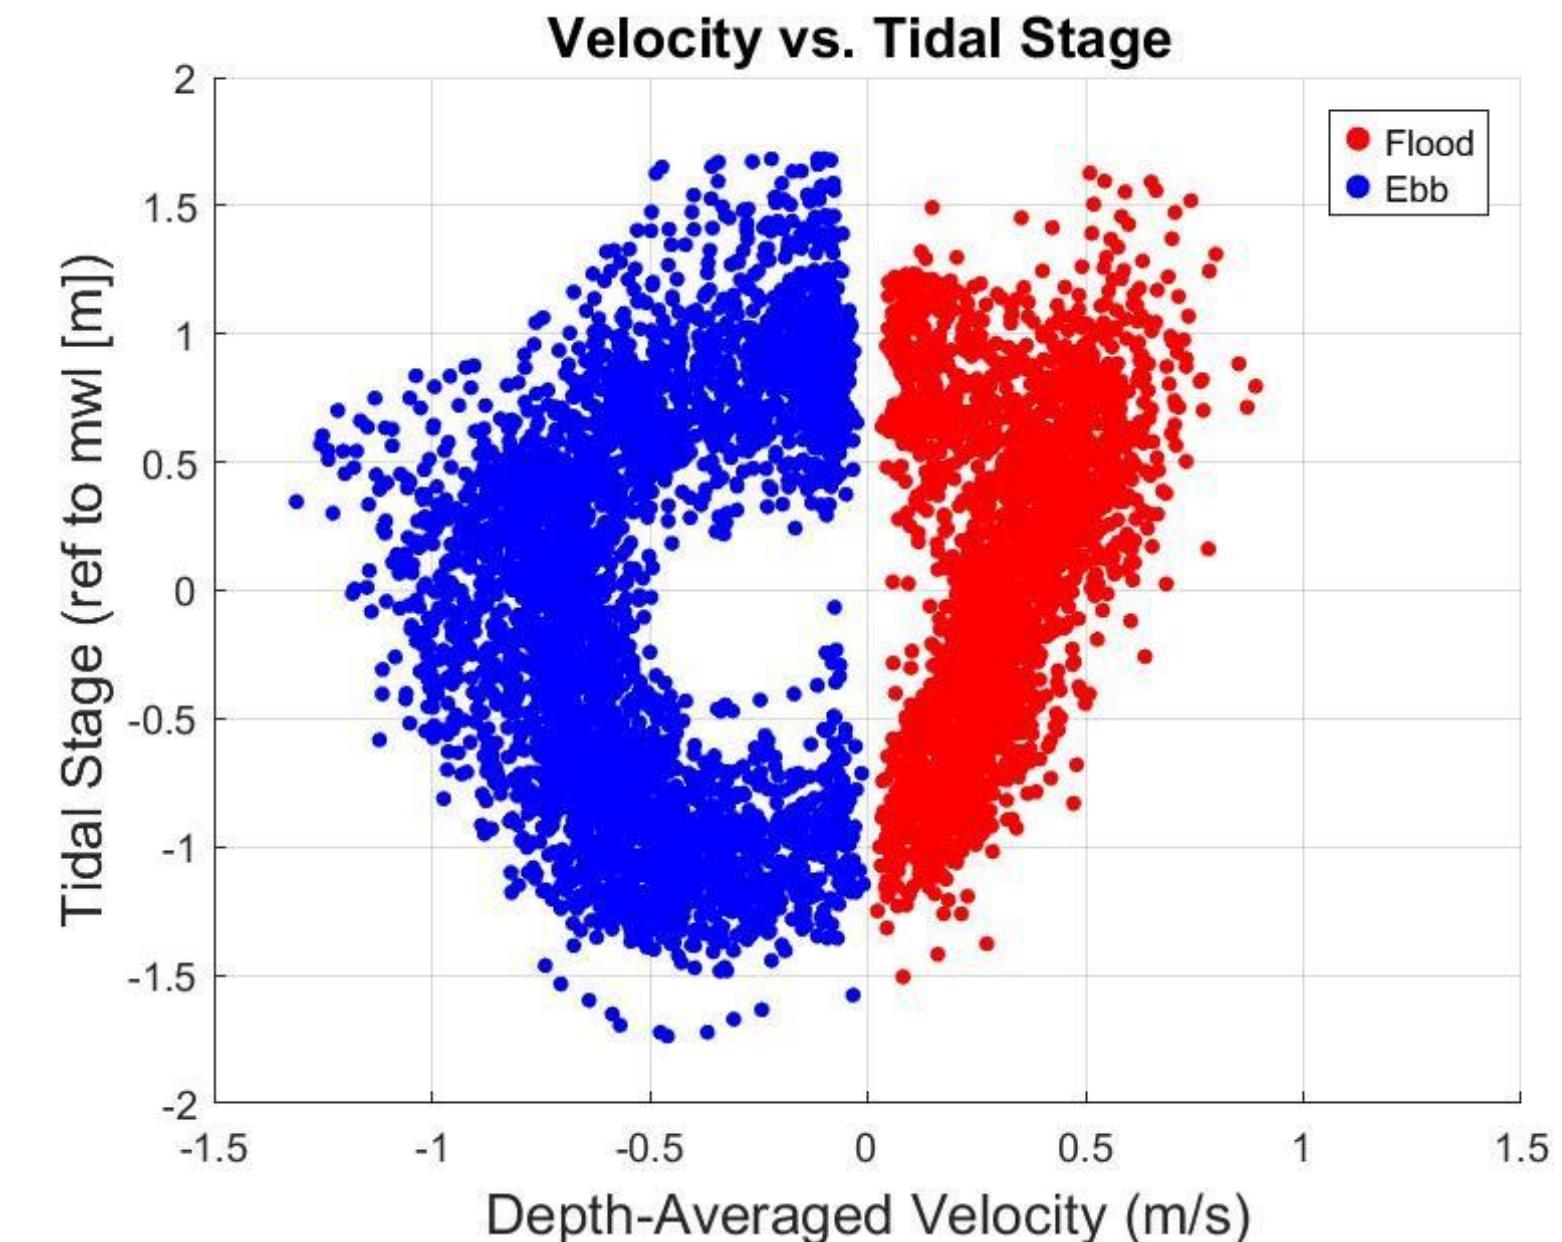

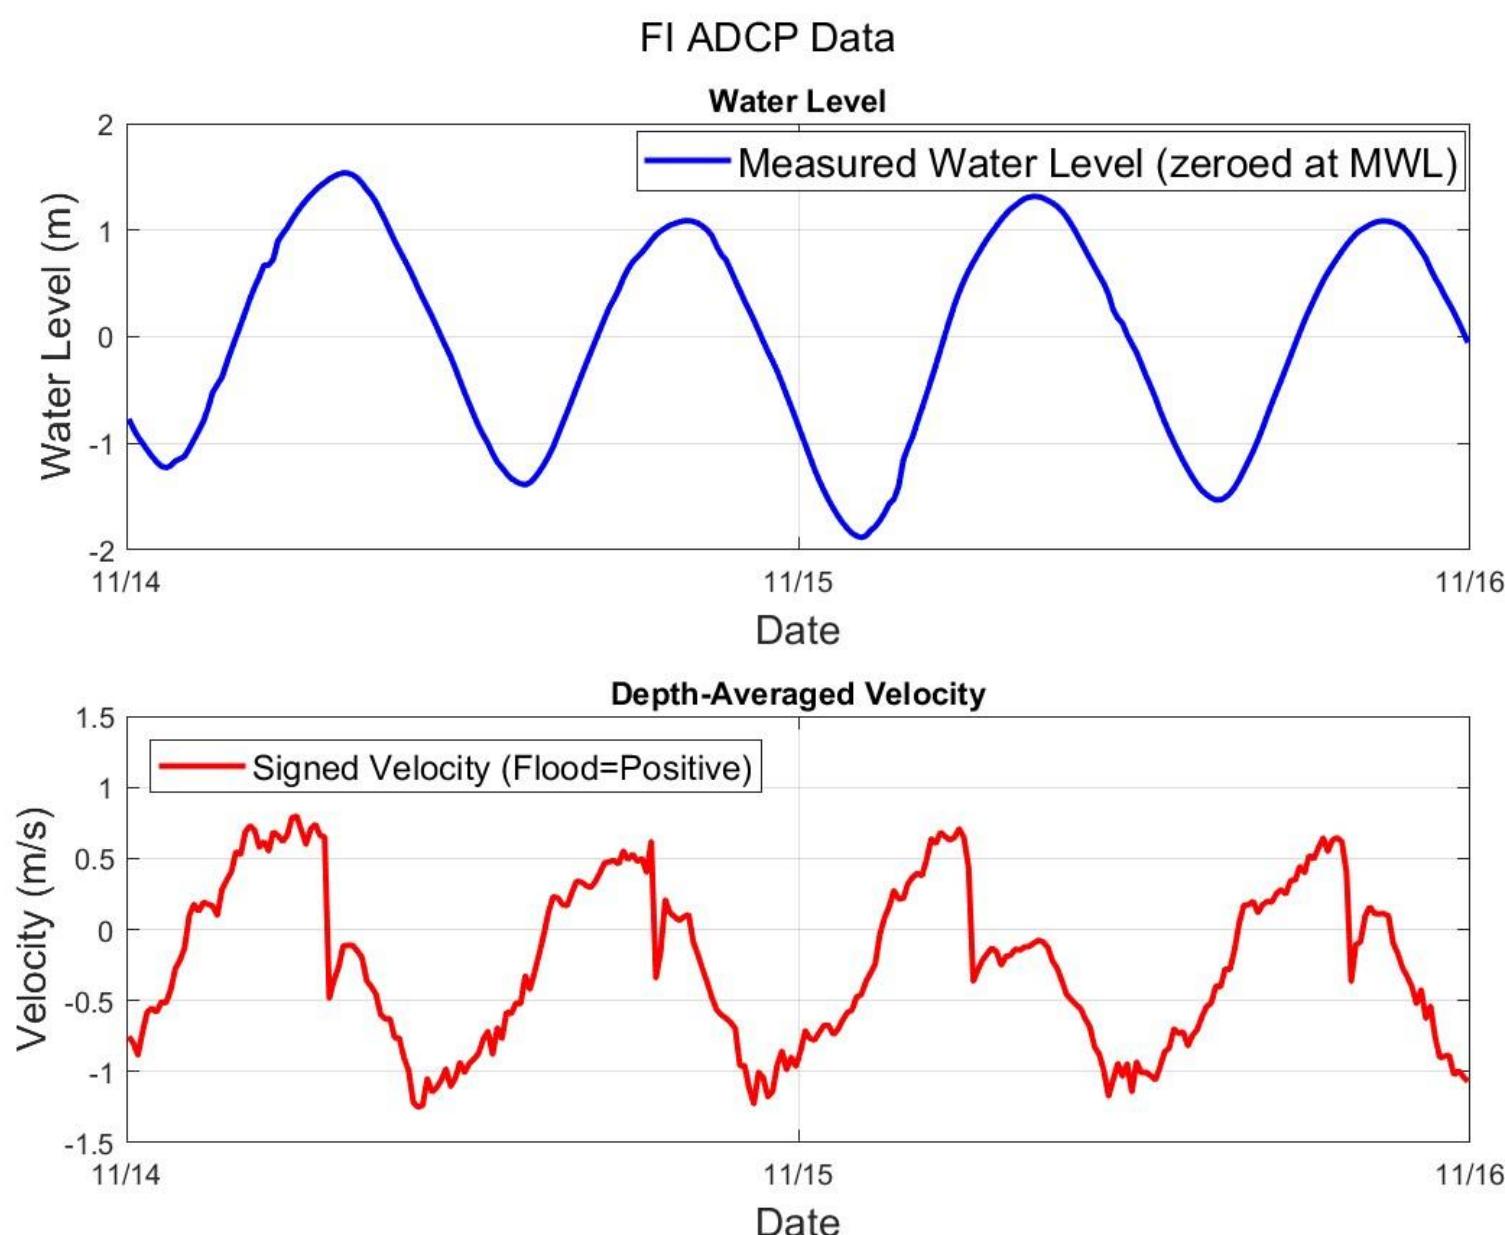

Sensitivity Analysis

- Duration Averaging
 - Converged to stable vertical profile at 3 minutes
- Proximity to TEC location
 - Consistent results within 20m of each TEC location

Overall Flow Characteristics

ADCP data

- Flood(+) Ebb(-)
- Ebb dominance
- Tidal elevation controls flow direction and magnitude

Evolution of MV Vertical Velocity Structure

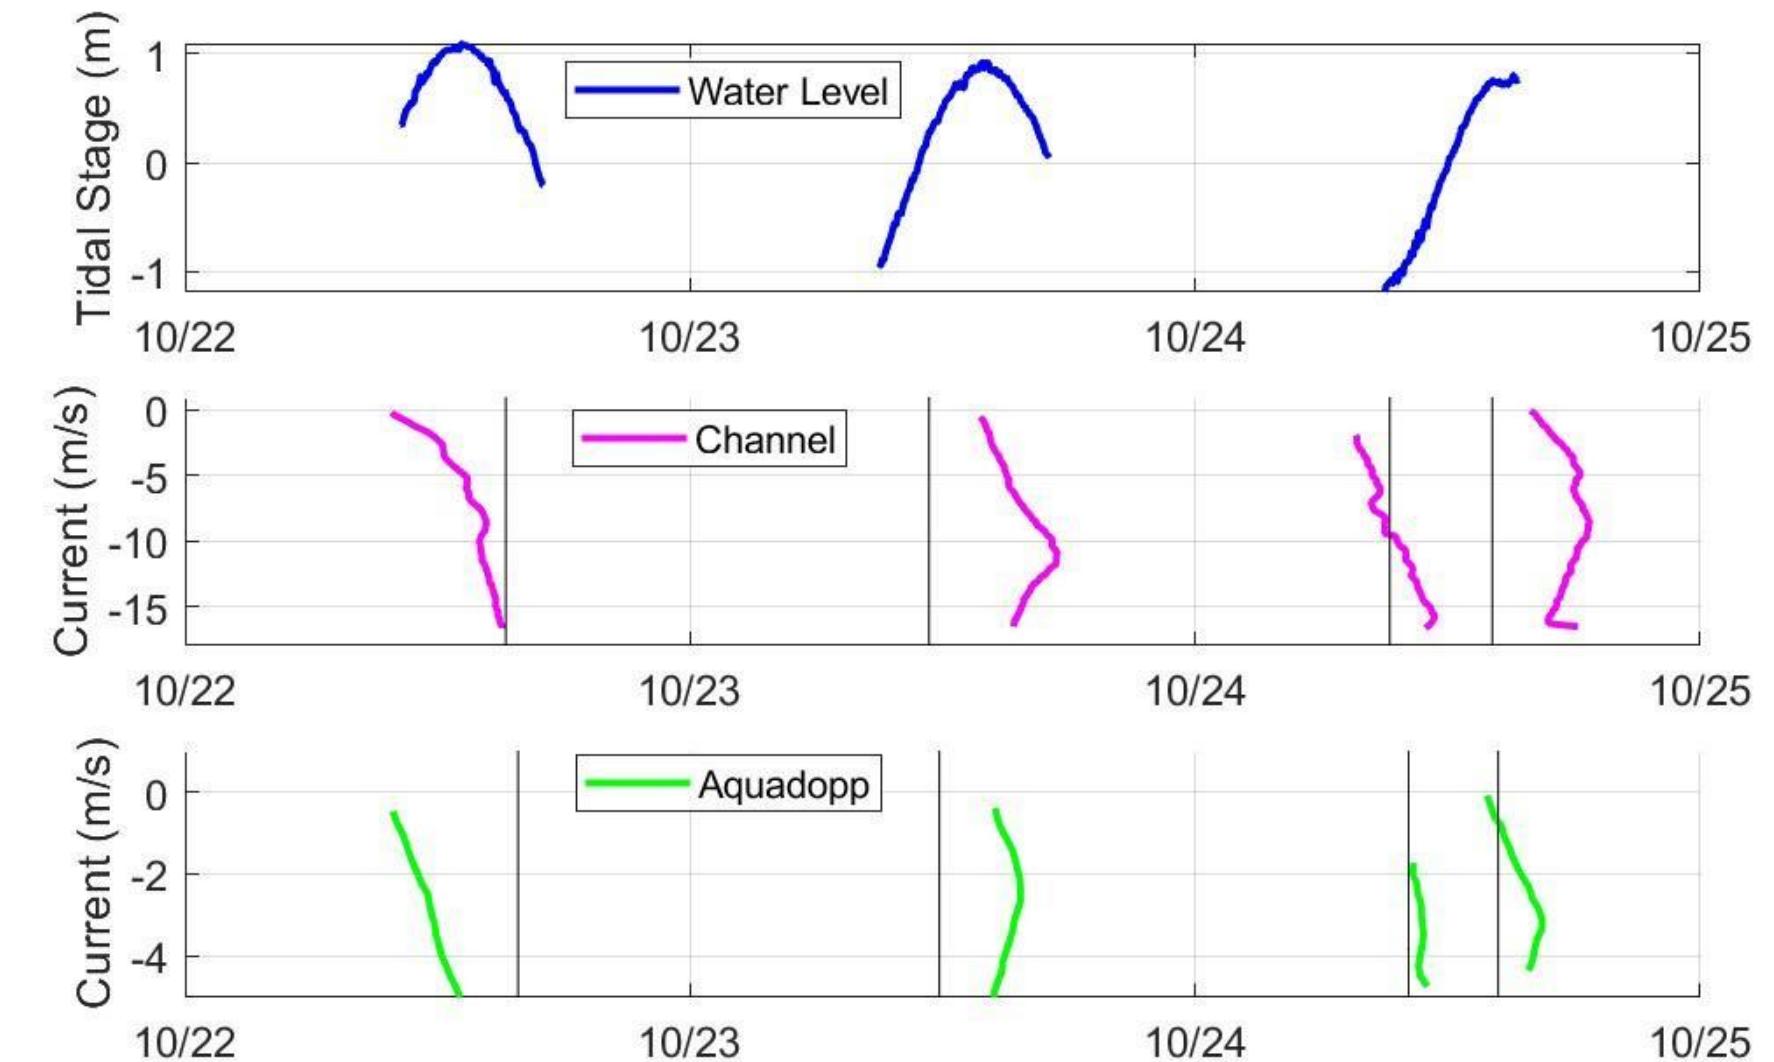

MV measurements

Slack tide: Flatter velocity profiles

Peak ebb: Stronger & sheared profiles

Peak flood: Lower peak, different shape

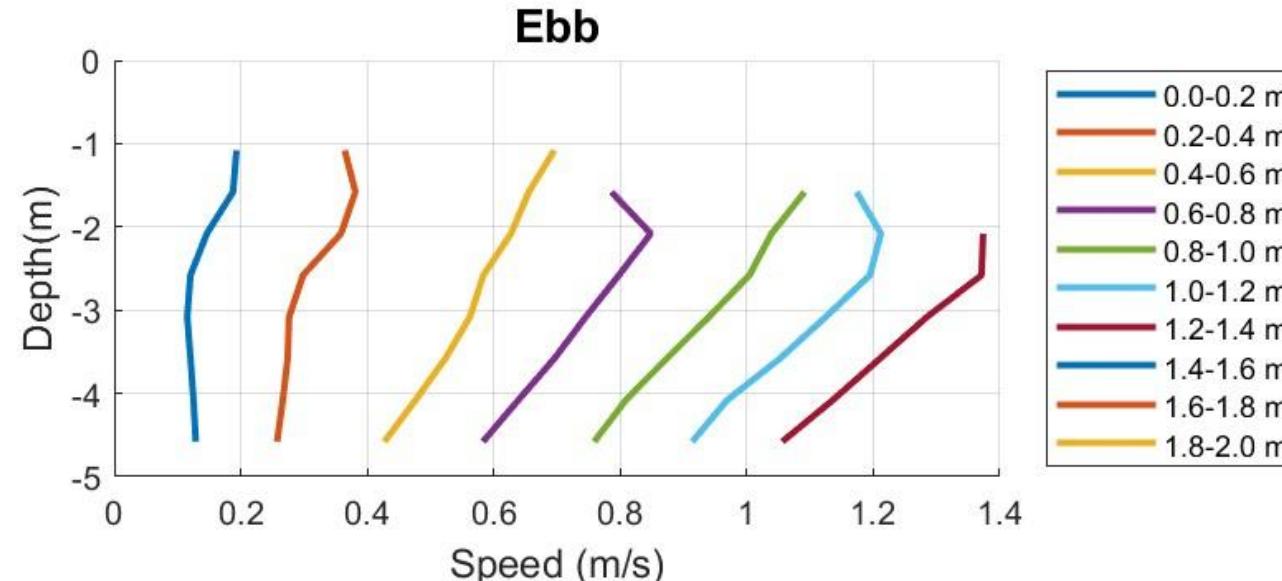

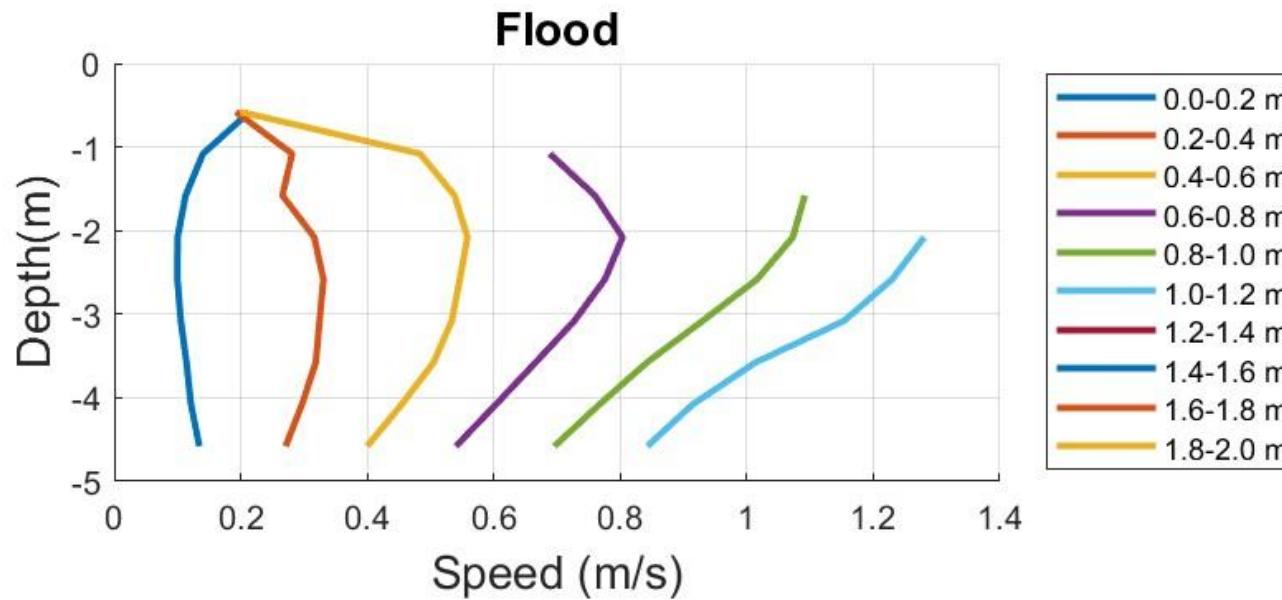

Importance of sampling across the full tidal range and throughout the water column

ADCP Vertical Velocity Structure

Average Velocity Profiles By Speed Bin

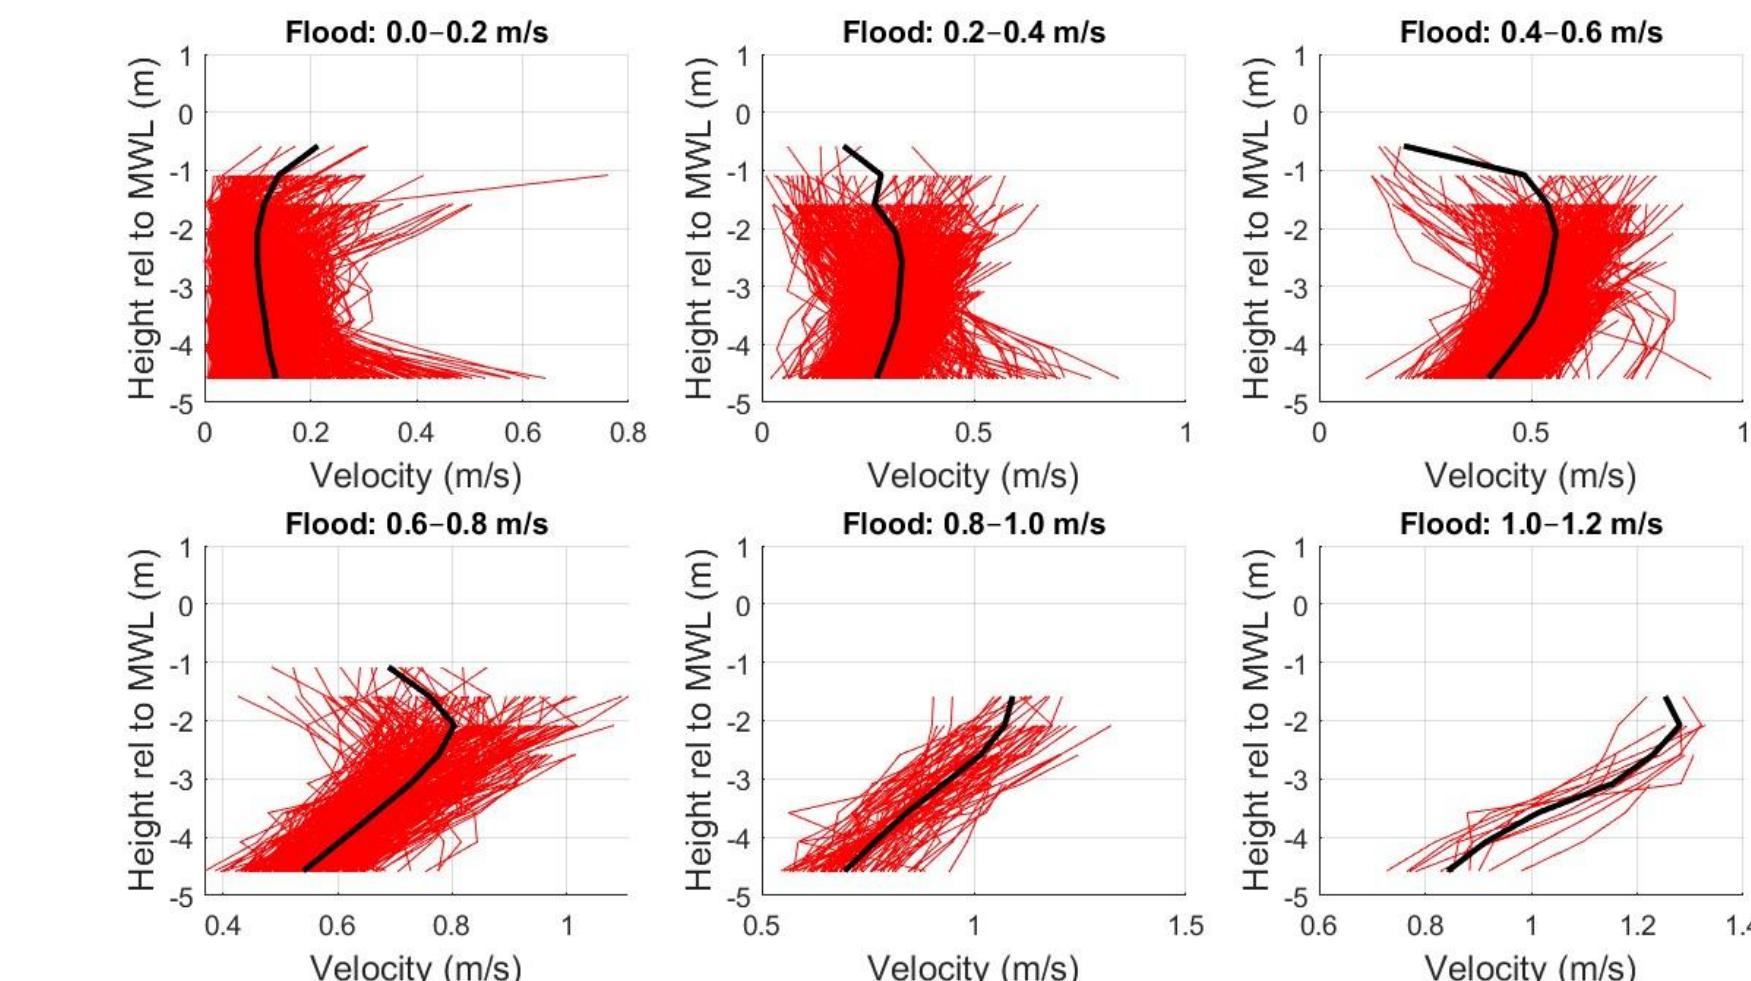

Speed bins

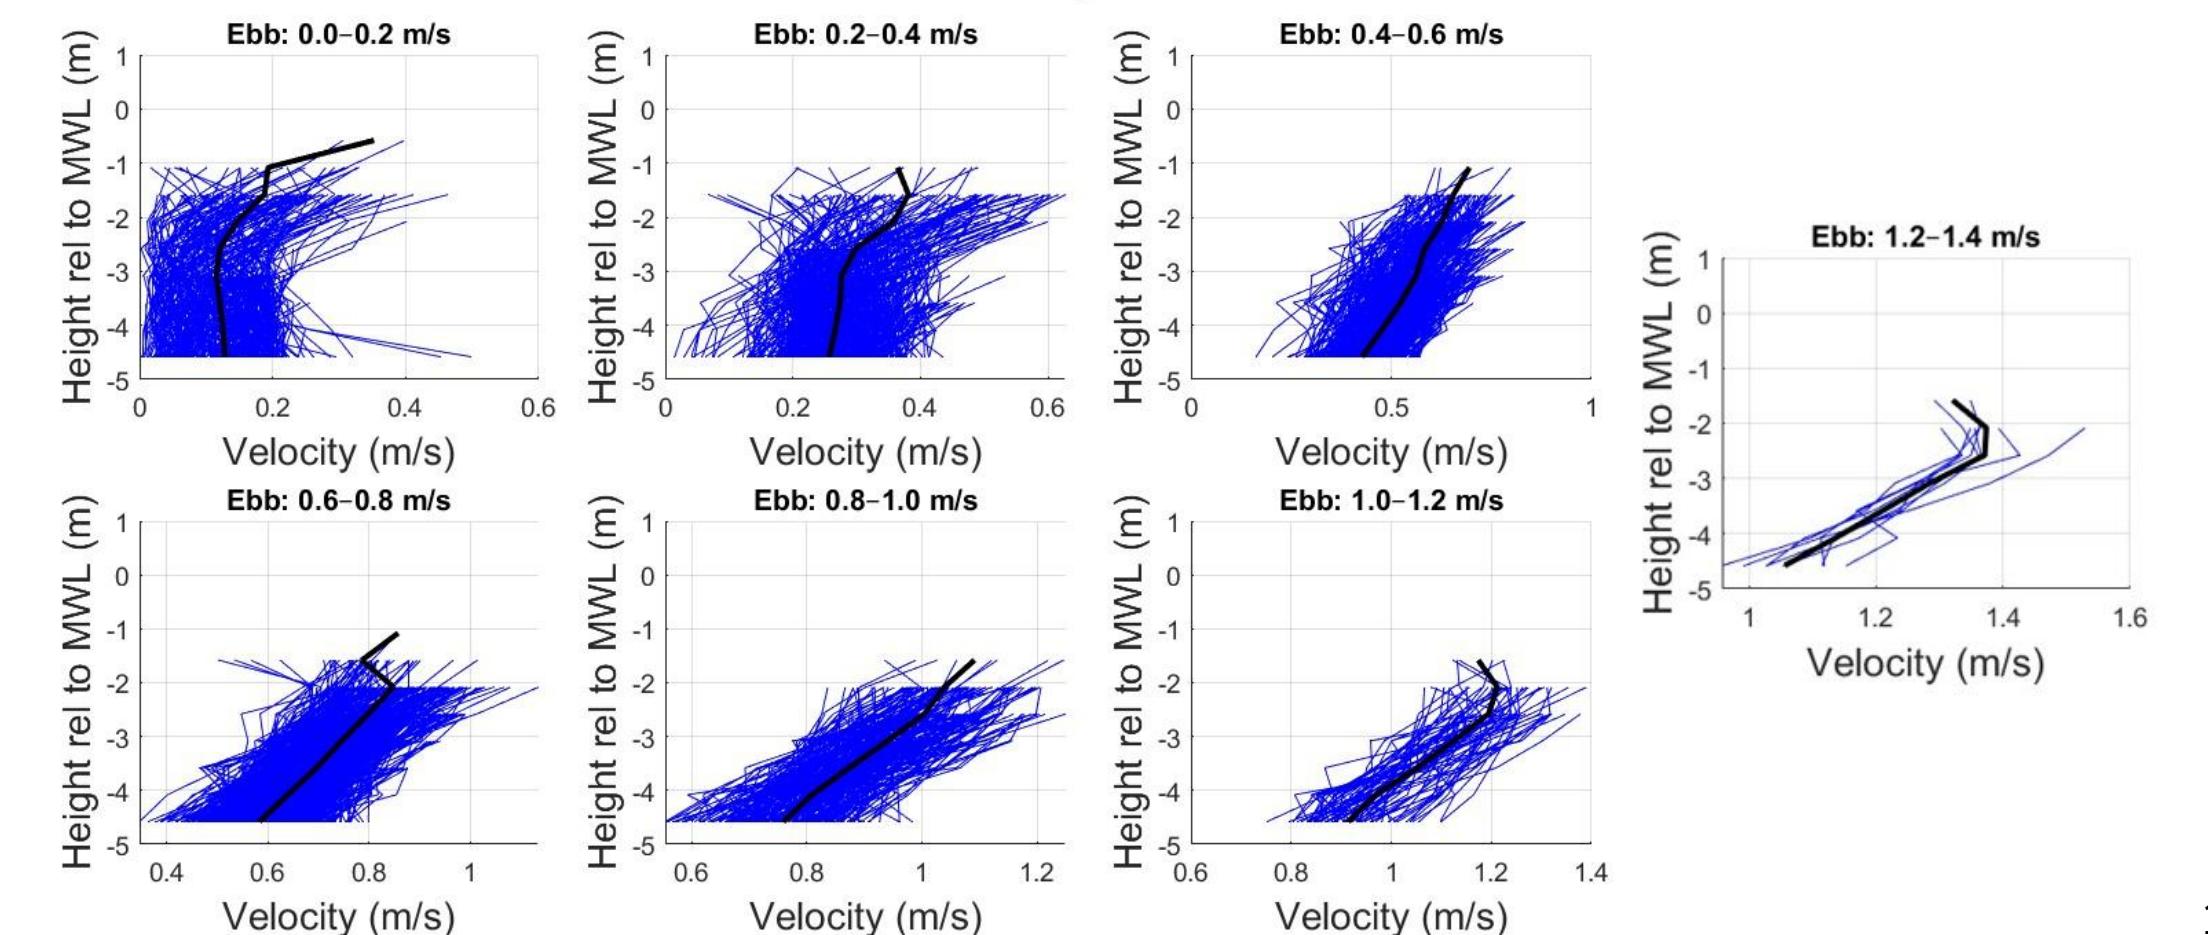

- Sorted into bins using depth-averaged speed
- Vertical variability in each bin

Higher speeds: strong vertical shear

All Flood Profiles Plotted Within Each Speed Bin

All Ebb Profiles Plotted Within Each Speed Bin

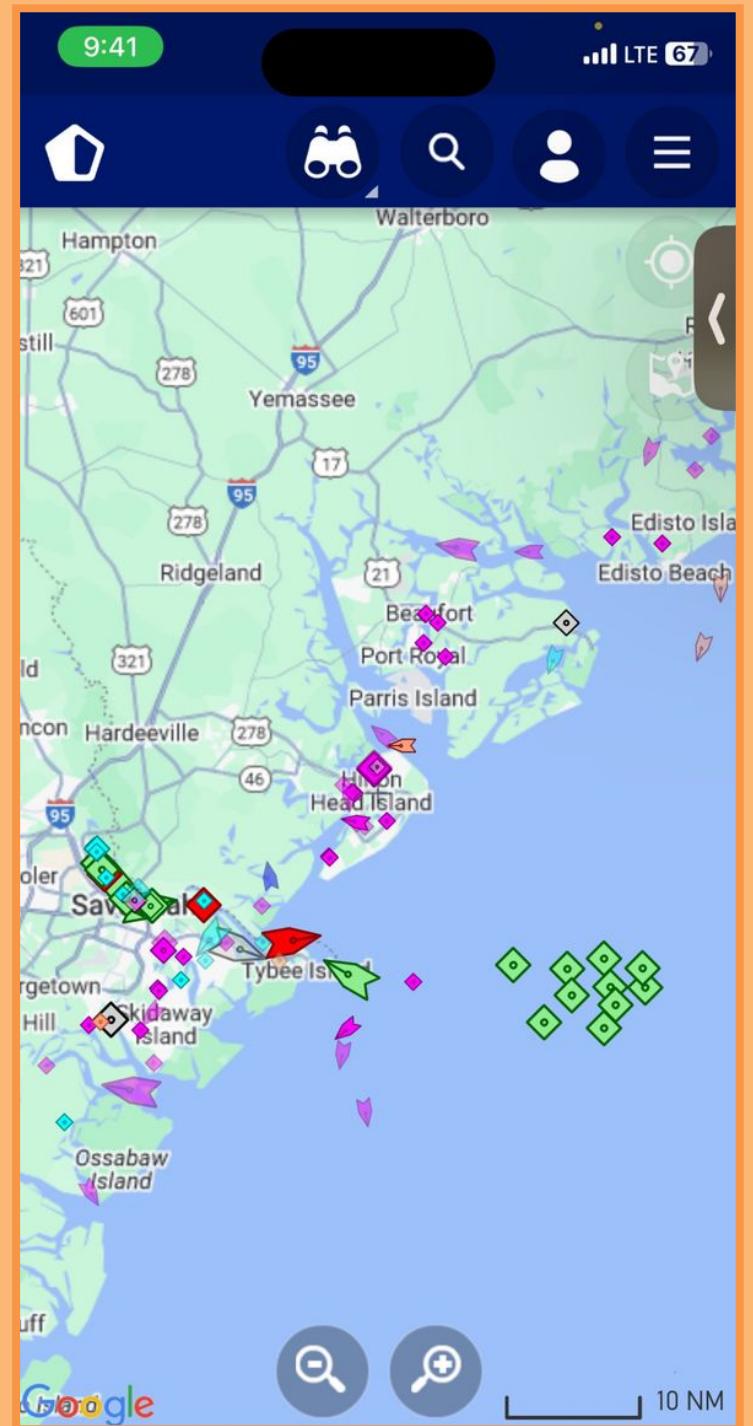

Wrapping Up

Conclusions

- **Field deployment worked**
 - Challenges: no divers to deploy frames - adjust frame structure and deployment method
- **HMS Overview**
 - 3-minute averaging & 20m proximity produced consistent results
- **Observations**
 - Challenges: ship wake & wind vs pontoon boat
- **FUTURE WORK**
 - Ebb dominant (tidal asymmetry)
 - Velocity profile asymmetry (ebb magnitude is stronger)
 - Strong velocity shear & variability in vertical profiles
 - Linear regression modeling
 - Use full-depth velocity profiles
 - Build regression model to predict velocity at the Energy Extraction Plane (EEP, eg. turbine height)
 - Why it matters
 - Applicable to anywhere with limited data
 - Reduces the need for FI measurements at every site
 - Keeps HMS cost-effective while still maintaining accuracy
 - Completed by September 2025
